In the fiber optic telecommunication system, a message is sent from one end through an electric cable to an encoder which transmits a signal through a glass fiber optic cable. It then travels through a repeater, back through the cable, into a decoder and through an electric cable into the phone line on the other end.

In addition, the fiber optics promises for increasing transmission rates. Infrared light covers a wide range of wavelengths and is generally used for all fiber optic communications. Visible light is used for very short range transmission using a plastic fiber or perhaps for fault testing where leaking visible light can be a diagnostic aid.

Fiber optics go back as far as Roman times, but the first was an "optical telegraph," which allowed operators to relay a message from one tower to the next by a series of lights mounted on the towers. This was invented in the 1790s by the French Chappe brothers. Great achievement was made in optical science over the course of the next century.
