Tacticity (from Greek τακτικός taktikos "of or relating to arrangement or order") is the relative stereochemistry of adjacent chiral centers within a macromolecule. The practical significance of tacticity rests on the effects on the physical properties of the polymer. The regularity of the macromolecular structure influences the degree to which it has rigid, crystalline long range order ...

Shape-memory polymers are elastic polymer networks that are equipped with suitable stimuli-sensitive switches^{11, 12}. The polymer network consists of molecular switches and netpoints (). The netpoints determine the permanent shape of the polymer network and can be of a chemical (covalent bonds) or physical (intermolecular interactions) nature.

Overview. A uniform, polymer (often referred to as a monodisperse polymer) is composed of molecules of the same mass. Nearly all natural polymers are monodisperse. Synthetic near-monodisperse polymer chains can be made by processes such as anionic polymerization, a method using an anionic catalyst to produce chains that are similar in length. This technique is also known as living polymerization.
